Problem 1 (graded by Kangchen) - 50 points+10 bonus points (a)10 points

The model parameter vector $\mathbf{m} = [x_s, y_s, z_s, P]^T$. The forward model is nonlinear, since the partial derivatives $\frac{\partial G}{\partial m_i}$ are not constant.

(b)10 points

For least squares problem, we introduce the objective function:

$$F = \frac{1}{2}(\boldsymbol{d} - \boldsymbol{g}(\boldsymbol{m}))^T(\boldsymbol{d} - \boldsymbol{g}(\boldsymbol{m})) = \frac{1}{2}\sum_{i=1}^n (d_i - \frac{Pz_s}{[(x_s - x_i)^2 + (y_s - y_i)^2 + z_s^2]^{3/2}})^2$$

define:

$$\eta_i = (x_s - x_i)^2 + (y_s - y_i)^2 + z_s^2$$

$$lx_i = x_i - x_i$$

$$ly_i = y_i - y_s$$

$$A_i = d_i - \frac{Pz_s}{[(x_s - x_i)^2 + (y_s - y_i)^2 + z_s^2]^{3/2}}$$

We write the $\hat{\boldsymbol{G}}$ matrix:

$$\hat{\boldsymbol{G}} = \begin{bmatrix} \frac{3Pz_x lx_1}{2\eta_1^{5/2}} & \frac{3Pz_x ly_1}{2\eta_1^{5/2}} & \frac{PR_1 - 3Pz_s^2}{2\eta_1^{5/2}} & \frac{z_s}{2\eta_1^{3/2}} \\ \frac{3Pz_x lx_2}{2\eta_2^{5/2}} & \frac{3Pz_x ly_2}{2\eta_2^{5/2}} & \frac{PR_2 - 3Pz_s^2}{2\eta_2^{5/2}} & \frac{z_s}{2\eta_2^{3/2}} \\ \dots & \dots & \dots & \dots \\ \frac{3Pz_x lx_n}{2\eta_n^{5/2}} & \frac{3Pz_x ly_n}{2\eta_n^{5/2}} & \frac{PR_n - 3Pz_s^2}{2\eta_n^{5/2}} & \frac{z_s}{2\eta_n^{3/2}} \end{bmatrix}$$

$$\boldsymbol{\nabla_m}F = (\boldsymbol{d} - \boldsymbol{g}(\boldsymbol{m}))^T \hat{\boldsymbol{G}} = [\sum_{i=1}^n (\frac{Pz_s}{\eta_i^{3/2}} - d_i)(\frac{3Pz_x lx_i}{\eta_i^{5/2}}), \sum_{i=1}^n (\frac{Pz_s}{\eta_i^{3/2}} - d_i)(\frac{3Pz_x ly_i}{\eta_i^{5/2}}), \sum_{i=1}^n (\frac{Pz_s}{\eta_i^{5/2}} - d_i)(\frac{PR_i - 3Pz_s^2}{\eta_i^{5/2}}), \sum_{i=1}^n (\frac{Pz_s}{\eta_i^{3/2}} - d_i)(\frac{z_s}{\eta_i^{3/2}})]^T$$

$$\boldsymbol{H}(F) = \boldsymbol{\nabla}_{\boldsymbol{m}}(\boldsymbol{\nabla}_{\boldsymbol{m}}F) = \boldsymbol{\nabla}(\hat{\boldsymbol{G}}^T(\boldsymbol{d} - \boldsymbol{g}(\boldsymbol{m}))) = \hat{\boldsymbol{G}}^T\hat{\boldsymbol{G}} - (\boldsymbol{d} - \boldsymbol{g}(\boldsymbol{m}))^T\boldsymbol{Q}$$

$$H_{----} = \hat{G}^T \hat{G}$$

$$\left(\boldsymbol{d} - \boldsymbol{g}(\boldsymbol{m}) \right)^T \boldsymbol{Q} = \sum_{i=1}^n \frac{A_i}{\eta_i 7/2} \begin{bmatrix} 15Pz_s lx_i^2 - 3Pz_s \eta_i & 15Pz_s lx_i ly_i & 3Plx_i \eta_i - 15Pz_s^2 lx_i & 3z_s lx_i \eta_i \\ & 15Pz_s ly_i^2 - 3Pz_s \eta_i & 3Ply_i \eta_i - 15Pz_s^2 ly_i & 3z_s dy_i \eta_i \\ sym & 15Pz_s^3 - 9Pz_s \eta_i & R_i^2 - 9z_s^2 \eta_i \end{bmatrix}$$

$$\begin{split} H_{xx} &= \sum_{i} 9P^{2}lx_{i}^{2}z_{s}^{2}\eta_{i}^{-5} - 15lx_{i}^{2}z_{s}A_{i}\eta_{i}^{-7/2} + 3Pz_{s}A_{i}\eta_{i}^{-5/2} \\ H_{zz} &= \sum_{i} (-6Pz_{s}^{2}\eta_{i}^{-5/2} + P\eta_{i}^{-3/2})^{2} - 15A_{i}Pz_{s}^{3}\eta_{i}^{-7/2} + 9A_{i}Pz_{s}\eta_{i}^{-5/2} \\ H_{xy} &= \sum_{i} 9P^{2}lx_{i}lyz_{i}^{2}z_{n}^{-5} - 15lx_{i}ly_{i}z_{s}A_{i}\eta_{i}^{-7/2} \\ H_{xy} &= \sum_{i} 3Plx_{i}z_{s}^{2}\eta_{i}^{-5} - 15lx_{i}ly_{i}z_{s}A_{i}\eta_{i}^{-7/2} \\ H_{xz} &= \sum_{i} -3Plx_{i}A_{i}\eta_{i}^{-5/2} - 15Plx_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3Plx_{i}z_{s}\eta_{i}^{-4} - 9P^{2}lx_{i}z_{s}^{3}\eta_{i}^{-5} \\ H_{xz} &= \sum_{i} -3Plx_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3Plx_{i}z_{s}\eta_{i}^{-4} - 9P^{2}lx_{i}z_{s}^{3}\eta_{i}^{-5} \\ H_{yp} &= \sum_{i} 3Ply_{i}z_{s}^{2}\eta_{i}^{-4} - 3ly_{i}z_{s}A_{i}\eta_{i}^{-5/2} \\ H_{yp} &= \sum_{i} -3Plz_{s}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-4} - 9Plx_{i}ly_{i}z_{s}\eta_{i}^{-5} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-4} - 9Plx_{i}ly_{i}z_{s}\eta_{i}^{-5} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-4} - 9Plx_{i}ly_{i}z_{s}\eta_{i}^{-5} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-4} - 9Plx_{i}ly_{i}z_{s}\eta_{i}^{-5} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-4} - 9Plx_{i}ly_{i}z_{s}\eta_{i}^{-5} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-4} - 9P^{2}lx_{i}z_{s}^{3}\eta_{i}^{-5} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-7/2} - 4\eta_{i}^{-7/2} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-7/2} - 4\eta_{i}^{-7/2} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-5/2} - 15Ply_{i}z_{s}^{2}\eta_{i}^{-7/2} + 3P^{2}ly_{i}z_{s}\eta_{i}^{-7/2} - 4\eta_{i}^{-7/2} \\ H_{yp} &= \sum_{i} -3Ply_{i}A_{i}\eta_{i}^{-7/2} - 15Ply$$

Note: this is the exact hessian, set $A_i = 0$ will make the approximated Hessian. The algorithm for finding solution is:

```
m{m} = m{m}_0 	ext{ (set initial guess)}
m{r} = (m{d} - m{g}(m{m}))
while m{r}^T m{r} > 	ext{errorbound}
.....compute Hessian m{H}(m{m}) and \hat{m{G}}^T m{r}
.....m{\Delta} m{m} = m{H}^{-1} \hat{m{G}}^T m{r}
.....m{m} = m{m} + m{\Delta} m{m}
.....m{r} = (m{d} - m{g}(m{m}))
end
```

(d)10 points

$$[x_s, y_s, z_s, P]^T = [8.137, -5.142, 11.507, 30.346]^T$$

(e)10 points

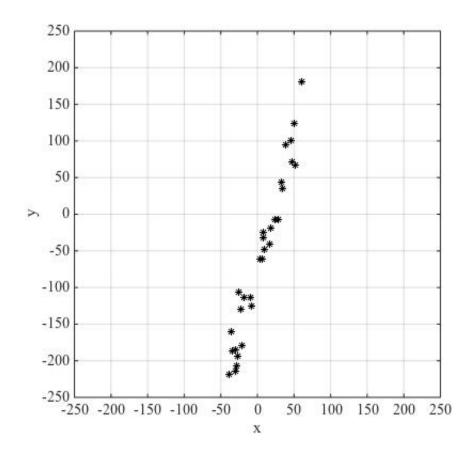

The standard deviations are $\sigma_{x_s} = 0.099670, \sigma_{y_s} = 0.137469, \sigma_{z_s} = 0.149719, \sigma_p = 0.691071$

There is a strong tradeoff relation between x_s, y_s, z_s . x_s, y_s are negatively related. x_s, z_s are positively related. z_s, y_s are negatively related. Note that we use z_s as depth value. It is always non-negative.

Problem 2 (graded by Yiran) - 50 points

(a) 4 points

(b) 6 points

 m_1 is the intercept with the y axis. From the plot, we estimate that it should be bounded by [-200, 50].

 m_2 is the slope of the line, we also estimate from the plot that it should be bounded by [1, 10]. As suggested in the problem, the arrays are better no larger than a few megabytes (1 double = 8 bytes) to avoid "out of memory" error. A 1000 by 1000 double-type matrix is 8 megabytes. Therefore, we can choose the discretization as $m_1 = [-200:0.1:50]$, and $m_2 = [1:0.01:10]$, so that the matrices of size length(m1) by length(m2) (e.g. the error matrix plotted in (d)), will be an appropriate size.

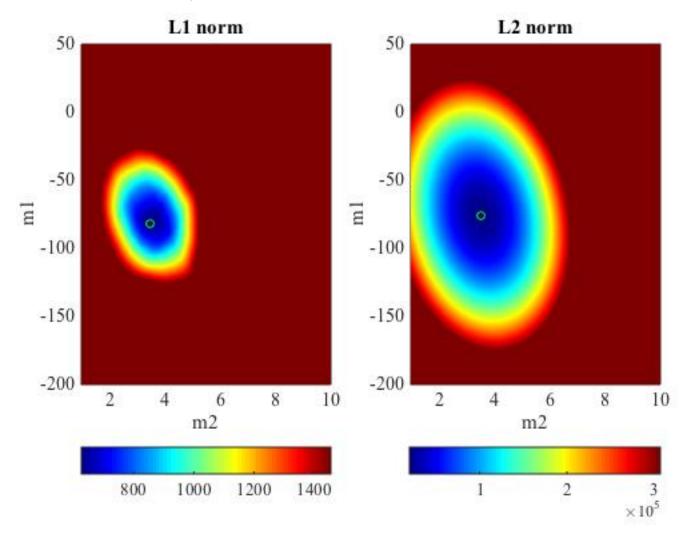

We can always shrink our model space and do a finer search as following steps.

(c) 6 points

(See attached MATLAB code.)

(d) 10 points

(See attached MATLAB code.)

(e) 4 points

The solutions with lowest misifit are

L2 norm: (-75.5, 3.53) L1 norm: (-81.9, 3.48)

(f) 10 points

(See attached MATLAB code.)

The least squares solution is: (-75.4631, 3.5301)

(g) 4 points

From (d), we infer that the model parameters are negatively correlated, and also the data error is underestimated (should be much larger than 0.1, which is the number your friend told you). The fact that there is (negative) correlation between model parameters is not part of the standard result. In addition, if the underestimated data error is used to evaluate the σ_m in the standard result, σ_m can also be underestimated.

(h) 6 points

(This is an open question.)

The L1 and L2 methods ("grid search") are more straighforward in showing the error distribution, thus the probability of the model parameters over the "full" model space.

The least-squares solution ("direct inversion") is fast, and gives the exact solution that minimizes L2 norm error. However, it is not as straightforward in showing all possible model parameters. In this small size problem, I would prefer the "grid search" method.

As the errors get bigger, the L1 norm method can be better, because it would be less likely to be affected by the outliers. Moreover, if there are several solutions that can minimize the error equally well, we can see it in the error map produced by the grid search method, and can choose one solution based on some priori information. Therefore, I will prefer L1 norm.
